# Managing and treating HOPE \*\*Tour New York Tour New York LYMPHEDEMA

Lymphedema is a chronic condition that impacts a number of cancer patients, especially those who have lymph nodes removed or damaged as part of their treatment. While lymphedema can be painful, even debilitating in some cases, the condition can be managed, prevented and, in some cases, reversed.

#### **SYMPTOMS**

The most common signs of lymphedema include:

**Aching** in

the neck,

shoulders,

spine or

hips

Pain, heat and/or

**redness** in the

affected area

**Persistent** 

in the skin

depressions

when pressed

## WHAT IS LYMPHEDEMA

- Lymphedema is swelling that results from excess **buildup of fluid** under the skin, most often in the arms and/or legs.
- The swelling is most commonly caused by the removal of or damage to the lymph nodes, creating a blockage that prevents fluid from draining sufficiently.
- The greater the number of lymph nodes affected, the higher the risk for developing lymphedema.

The condition can be caused by:

- Cancer tumors or lesions that cause blockages of the lymph system
- Surgery and/or radiation therapy to treat cancer
- Recurrence or spread **of a tumor** to the lymph nodes
- Infection and/or **injury** to the lymphatic vessels
- Inflammation or scarring
- Temporary loss of lymphatic function
- Blood clot blocking a vein

### **Swelling,** most often in the arms, hands, fingers, shoulders, chest or legs

A feeling of

tightness or

stiffness in the skin

**Decreased** movement or **flexibility** in the hand, wrist or ankle

**Untreated** lymphedema can lead to decreased function and mobility in the affected area, skin breakdown, infection and other complications.

# Who does lymphedema affect?

- The condition is **most commonly associated** with breast cancer patients, since the surgical removal of lymph nodes and the use of radiation therapy are common treatments to prevent breast cancer from spreading to nodes under the arm.
- But lymph nodes are also found in other parts of the body, such as the neck, abdomen and groin. That's why lymphedema affects both men and women and can result from treatment for other cancers, such as:
  - Prostate cancer
- Lymphoma
- Gynecological cancers
- Melanoma
- Head and neck cancers

# Stages of progression

Lymphedema occurs in four stages, the last three of which are active:

#### **STAGE 0** (latency):

The transport capacity of the lymphatic system is reduced due to a mechanical dysfunction caused by trauma such as surgery, radiation or missing lymph nodes, but swelling isn't visible.

#### (mild): Some swelling becomes noticeable.

## **STAGE 2** (moderate):

The tissue starts to harden. and swollen,

## **STAGE 3** (severe):

The tissue is harder, and the affected limb becomes very large a condition known as lymphostatic elephantiasis.

A weakness or heavy feeling in the arms or legs

**Tight-fitting** 

ring, watch, clothes or

shoes

## **PREVENTION & TREATMENT**

With early diagnosis and proper care and treatment, lymphedema may be prevented or controlled, and with surgical options available to some patients, possibly even reversed.

#### **PREVENTING** LYMPHEDEMA:

If a cancer patient is deemed at risk for lymphedema, a number of options may be recommended to keep the condition at bay, including:

 A sentinel lymph node **biopsy** prior to surgery to identify lymph nodes for removal, while helping to preserve remaining

lymph nodes

 Gentle range-ofmotion exercises. massage, skin care, light exercises and education techniques to stimulate

the lymphatic system

 Compression bandages, pumps or garments (e.g., sleeves, stockings) to help prevent additional fluid from accumulating in the tissue

#### **MANAGING** LYMPHEDEMA:

Once signs of lymphedema appear, steps can be taken to manage the symptoms and prevent them from progressing. Options include:

 Compression bandages, pumps or garments (e.g., sleeves, stockings) to help prevent additional fluid from accumulating in the tissue

## Lymph drainage

massage technique is designed to activate the pumping action of your lymphatic system. The pumping action reduces and, in some cases, prevents fluid buildup.

therapy: This specialized

 Le duc manual lymph drainage: This option employs a combination of manual lymph drainage with multi-layer bandaging and a compression pump, to clear excess lymphatic fluids from the body by activating the pumping action of the lymphatic system.

## **SURGICAL OPTIONS:**

After non-surgical therapeutic approaches have been exhausted, two state-of-the-art surgical options may also be available to treat lymphedema.

 Vascularized lymph node transfer surgery: This is an intricate microsurgical procedure used to treat patients with advanced lymphedema affecting the skin tissue in the arms or legs.

Plastic surgeons transfer working lymph nodes from another part of the body, typically the upper groin or lower abdomen, to the damaged site.

The existing blood vessels supplying the nodes are then divided and connected at the site the lymph nodes are needed. Reverse lymphatic mapping is used to reduce the chance of lymphedema occurring in the areas

where lymph nodes were harvested.

#### Lymphaticovenular bypass surgery: This is an intricate super-microsurgical

procedure used to treat patients with mild to moderate lymphedema.

The plastic surgeons perform the surgery by locating damaged lymphatic vessels directly beneath the skin in the affected area of the body.

Then the surgeons redirect, or shunt,

fluid from damaged lymphatic vessels to neighboring tiny veins called "venules," by connecting the working segments of the lymphatic vessels to the venules to allow excess fluid to drain into the bloodstream and reduce pressure in the affected area.
